

THE MEX MODEL

Introduction

In trading, analysis paralysis and lack of decision-making usually come from knowing too much and trying to process too many variables at once.

That is why I started shifting my focus toward:

- Higher timeframe execution
- Less decision making
- Less manipulation
- More structured expansion trading

The hard part in trading often comes from:

- Using too much information
- Constantly switching timeframes
- Trying to validate one idea with another idea
- Entering too discretionarily

So I wanted a framework that:

- Keeps the core logic of what we are trading
- Simplifies execution
- Removes unnecessary timeframe switching
- Allows us to focus only on the important price delivery

This is where the MEX Model comes from.

The MEX Model Itself

Manipulation → Expansion Model

The entire model is built on one core idea:

Manipulation creates expansion.

Every reversal phase is essentially:

- A manipulation
- Followed by expansion

This applies to:

- Daily candles
- 6H candles
- Intraday price delivery

The Timeframes of the MEX Model

1. Daily Timeframe — Bias

The Daily timeframe is used for:

- Bias
- Candle closures
- Gaps
- Overall direction
- Weekly Profiles

The whole idea is:

Trade within the direction of the daily candle.

2. 6H Timeframe — Structural Timeframe

The structural timeframe of this model is the 6H chart.

Why 6H?

Because it structures the day perfectly around the New York session.

The sessions become:

- 18:00 → 00:00
- 00:00 → 06:00
- 06:00 → 12:00

This gives us:

- Overnight information
- London session information
- The full New York expansion window

The Timeframes of the MEX Model

Why 6H Works Better

The 6H candle captures continuation through the lens of the 6:00 AM open.

This means:

- If price already created the high/low of the day overnight:
 - We trade continuation early
- If price has not reversed yet:
 - We trade the NY reversal within the same candle

Unlike the 4H chart:

- You are not trapped between candle opens
- You are not forced into fast decisions, you are not missing the first part of price delivery.

The 6H candle gives:

One complete execution window 6:00am EST to 12:00pm EST.

Why Skip 1H / 30M Intermediate Timeframes

The 1H and 30M candles are still moving within:

- The Daily candle structure/6H candle structure.

But constantly using them creates:

- Over-analysis, too many decisions
- Micro-management, conflicting information

The purpose of the MEX Model is:

Simplicity through higher timeframe structure.

- We use the 6H swing point/6H manipulation
- Then execute only when necessary

The Timeframes of the MEX Model

The entry timeframes are:

- 15M,7M.

And nothing else.

Why 15M?

The 15M timeframe:

- Captures orderblocks very precisely
- Gives cleaner CISDs, Filters noise
- Allows better awareness of manipulation

Example:

- If 9:30 manipulates price
- The 15M gives enough time to assess:
 - Was it true manipulation?

Lower timeframes like:

- 5M,3M

Become too noisy when trading a 6H candle.

They create:

- Too many opposing runs, Emotional entries, Over-management.

Why 7M?

Sometimes:

- The 15M CISD candle expands too aggressively
- The entry becomes inefficient

So dividing the 15M candle into two gives:

The 7M timeframe

This allows:

- Earlier entries
- Better RR

Step 1 — Daily Bias

Bias is derived through:

- Candle closures
- Daily manipulation
- Trading expansion after reversal

The reversal phase itself is:

Manipulation before expansion.

Step 2 — 6H Candle Logic

Scenario 1 — Reversal Prior to NY

If we expect an:

- OLHC daily candle

Then:

- Overnight session should create the low (18:00 or 00:00).
- 6:00 AM candle should expand away from that manipulation

This becomes:

NY continuation.

Scenario 2 — NY Reversal

If there is:

- No clear manipulation
- No trustworthy reversal

Then:

Wait for the 6:00 AM candle to manipulate the range.

Usually through:

- 8:30
- 9:30 Drivers

Then trade:

Manipulation → Expansion.

London Reversal

NY Reversal

Step 3 — Entry Logic

Scenario 1 — Reversal Prior to NY

if there is a reversal prior to the NY session (18:00 or 00:00 manipulation).

then We trade the Opposing Run which is creating the low of the 6:00am 6hr candle or trade any continuation orderblock, after the initail opposing run.

Scenario 2 — NY Reversal

If there is no Manipulation Prior to the 6:00 am 6hr candle then we wait for the Drivers to create the high or low of the 6:00am 6hr candle and we trade the First reversal entry Using CISD.

if that Reversal has a larger stoploss then we trade the Retest of it or Wait for another opposing run.

Trading Window & Targets

Main execution window:

- 6:00 AM → 12:00 PM

Personal execution:

- Post 9:00 / 9:30

Because:

- Drivers are active
- Manipulation becomes visible
- Expansion becomes clearer

Can PM Session Be Traded?

Yes.

But:

- Most expansion already occurred
- Probability becomes lower

If trading PM:

- Use the 6:00 → 12:00 candle as reference

Expansion Days target:

- Opposing liquidity

Large wick days target:

- Daily open

Risk Management

- Starting framework:
- Fixed 2R
- If holding expansion:
- Manually close at the end of the 6H candle (12:00 PM).
